On extended Dirichlet spaces
and the space of BL functions

Masatoshi Fukushima

Abstract
We first formulate the notions of the Dirichlet form and the extended
Dirichlet space without assuming any topology on the underlying space. We
next study the space of BL functions on an Euclidean domain in relation
to the extended Dirichlet space of the Sobolev space of order 1 as well as
an extension of the time changed transient Brownian motion by reflection at
infinity.

The (symmetric) Dirichlet space and the Dirichlet form were introduced by A.
Beurling and J. Deny [1] in 1959 and then the extended Dirichlet space was defined
by M.L. Silverstein [15] in 1974. In both cases, the underlying space was assumed to
be a locally compact Hausdorff topological space. We first formulate them without
assuming any topology on the underlying space using an idea of B. Schmuland [13].

The notion of the extended Dirichlet space serves as a useful tool to give criteria
for the transience and recurrence of the associated Markovian semigroup. Besides,
it plays the role of an invariant in describing the time changes of the process or.equivalently, the exchanges of the underlying measure, and it enables us to formulate
its maximal extension called the reflected Dirichlet space in transient case.

The space of BL (Beppo Levi) functions on an Euclidean domain was introduced
and studied in J. Deny and J.L. Lions [8] in 1953-4 that preceded [1]. The second
aim of the present paper is to examine this space in relation to the above mentioned
concepts for the Brownian motion, producing a new extension of it at infinity.

1 Extended Dirichlet spaces

Let \((E, \mathcal{B}(E))\) be a measurable space and \(m\) be a \(\sigma\)-finite measure on it. Numerical
functions \(f, g\) on \(E\) are said to be \(m\)-equivalent (\(f = g \mod m\) in notation) if \(f = g\) \(m\)-a.e.

**Definition 1.1** For \(1 \leq p \leq \infty\), a linear operator \(L\) on \(L^p(E; m)\) is called Markovian if

\[
0 \leq f \leq 1 \mod m, \ f \in \mathcal{D}(L) \implies 0 \leq Lf \leq 1 \mod m.
\]

A real function \(\varphi\), namely, a mapping from \(\mathbb{R}\) to \(\mathbb{R}\), is said to be a normal contraction if

\[
\varphi(0) = 0, \quad |\varphi(s) - \varphi(t)| \leq |s - t|, \quad \forall s, t \in \mathbb{R}.
\]

†Osaka University, e-mail: fuku2@mx5.canvas.ne.jp
A function defined by $\varphi(t) = (0 \lor t) \land 1$, $t \in \mathbb{R}$, is a normal contraction which is called the unit contraction. For any $\epsilon > 0$, a real function $\varphi_\epsilon$ satisfying the next condition is a normal contraction:

$$
\varphi_\epsilon(t) = t, \forall t \in [0,1]; 
-\epsilon \leq \varphi_\epsilon(t) \leq 1 + \epsilon, \forall t \in \mathbb{R}, 

s < t \rightarrow 0 \leq \varphi_\epsilon(t) - \varphi_\epsilon(s) \leq t - s, \forall s, t \in \mathbb{R}.
$$

(1.1)

**Definition 1.2** A symmetric form $(\mathcal{E}, \mathcal{D}(\mathcal{E}))$ on $L^2(E;m)$ is called Markovian if, for any $\epsilon > 0$, there exists a real function $\varphi_\epsilon$ satisfying (1.1) and

$$
 f \in \mathcal{D}(\mathcal{E}) \implies g = \varphi_\epsilon \circ f \in \mathcal{D}(\mathcal{E}), \quad \mathcal{E}(g,g) \leq \mathcal{E}(f,f).
$$

(1.2)

A closed symmetric form $(\mathcal{E}, \mathcal{F})$ on $L^2(E;m)$ is called a Dirichlet form if it is Markovian. In this case, the domain $\mathcal{F}(= \mathcal{D}(\mathcal{E}))$ is said to be a Dirichlet space.

**Theorem 1.3** Let $(\mathcal{E}, \mathcal{F})$ be a closed symmetric form on $L^2(E;m)$ and $\{T_t\}_{t \geq 0}$, $\{G_\alpha\}_{\alpha > 0}$ be the strongly continuous contraction semigroup and resolvent on $L^2(E;m)$ generated by $(\mathcal{E}, \mathcal{F})$, respectively. Then the next conditions are mutually equivalent:

(a) $T_t$ is Markovian for each $t > 0$.

(b) $\alpha G_\alpha$ is Markovian for each $\alpha > 0$.

(c) $(\mathcal{E}, \mathcal{F})$ is a Dirichlet form on $L^2(E;m)$.

(d) The unit contraction operates on $(\mathcal{E}, \mathcal{F})$:

$$
 f \in \mathcal{F} \implies g = (0 \lor f) \land 1 \in \mathcal{F}, \quad \mathcal{E}(g,g) \leq \mathcal{E}(f,f).
$$

(e) Every normal contraction operates on $(\mathcal{E}, \mathcal{F})$: for any normal contraction $\varphi$

$$
 f \in \mathcal{F} \implies g = \varphi \circ f \in \mathcal{F}, \quad \mathcal{E}(g,g) \leq \mathcal{E}(f,f).
$$

This theorem can be shown in exactly the same way as the proof of [9, Th.1.4.1] except for the implication (a) $\Rightarrow$ (e), which follow however from the more general theorem formulated below. In what follows, we occasionally use for a Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2(E;m)$ the notations $\|f\|_\mathcal{E} = \sqrt{\mathcal{E}(f,f)}$, $f \in \mathcal{F}$.

**Definition 1.4** Let $(\mathcal{E}, \mathcal{F})$ be a closed symmetric form on $L^2(E;m)$. Denote by $\mathcal{F}_e$ the totality of $m$-equivalence classes of all $m$-measurable functions $f$ on $E$ satisfying the next condition:

$$
|f| < \infty [m], \exists \{f_n\} \subset \mathcal{F}, \lim_{n,n' \to \infty} \|f_n - f_{n'}\|_\mathcal{E} = 0, \lim_{n \to \infty} f_n = f [m].
$$

(1.3)

$\{f_n\} \subset \mathcal{F}$ in the above is called an approximating sequence of $f \in \mathcal{F}_e$. We call the space $\mathcal{F}_e$ the extended space attached to $(\mathcal{E}, \mathcal{F})$. When the latter is a Dirichlet form on $L^2(E;m)$, the space $\mathcal{F}_e$ will be called its extended Dirichlet space.

**Theorem 1.5** Let $(\mathcal{E}, \mathcal{F})$ be a closed symmetric form on $L^2(E;m)$ and $\mathcal{F}_e$ be the extended space attached to it. If the semigroup $\{T_t; t > 0\}$ generated by $(\mathcal{E}, \mathcal{D}(\mathcal{F}))$ is Markovian, then the followings are true:

2
(i) For any \( f \in \mathcal{F}_e \) and for any approximating sequence \( \{f_n\} \subset \mathcal{F} \) of \( f \), the limit 
\[ \mathcal{E}(f, f) = \lim_{n \to \infty} \mathcal{E}(f_n, f_n) \]
exists independently of the choice of an approximating sequence \( \{f_n\} \) of \( f \).

(ii) Every normal contraction operates on \((\mathcal{F}_e, \mathcal{E})\): for any normal contraction \( \varphi \)
\[ f \in \mathcal{F}_e \implies g = \varphi \circ f \in \mathcal{F}_e, \quad \mathcal{E}(g, g) \leq \mathcal{E}(f, f). \]

(iii) \( \mathcal{F} = \mathcal{F}_e \cap L^2(E; m) \). In particular, \((\mathcal{E}, \mathcal{F})\) is a Dirichlet form on \( L^2(E; m) \).

Assertions (ii) and (iii) of this theorem imply the implication \((a) \Rightarrow (e)\) in Theorem 1.3. Before giving the proof of Theorem 1.5, we shall fix a Markovian contractive symmetric linear operator \( T \) on \( L^2(E; m) \) and make some preparatory observations.

By the linearity and the Markovian property of \( T \) on \( L^2(E; m) \cap L^\infty(E; m) \),
\[ f_1, f_2 \in L^2 \cap L^\infty, \quad 0 \leq f_1 \leq f_2 \] \[ \implies 0 \leq Tf_1 \leq Tf_2 \leq \|f_2\|_\infty \|m\].

Due to the \( \sigma \)-finitness of \( m \), we can construct a Borel function \( \eta \in L^1(E; m) \) which is strictly positive on \( E \). If we put \( \eta_n(x) = (n\eta(x)) \wedge 1 \), then \( 0 < \eta_n \leq 1 \), \( \eta_n \uparrow 1 \), \( n \to \infty \). Hence we can define an extension of \( T \) from \( L^2(E; m) \cap L^\infty(E; m) \) to \( L^\infty(E; m) \) by
\[ T \begin{cases} T(f(x)) = \lim_{n \to \infty} T(f \cdot \eta_n)(x), & m\text{-a.e. } x \in E, \quad f \in L^\infty(E; m), \\ Tf = Tf^+ - Tf^-, & f \in L^\infty(E; m), \quad f = f^+ - f^- . \end{cases} \]
(1.4)

By the symmetry of \( T \), \( \langle g, Tf \cdot \eta \rangle = \langle Tg, f \cdot \eta \rangle \), \( g \in bL^1(E; m) \), and we let \( n \to \infty \) to see that the function \( Tf, \ f \in L^\infty(E; m) \), defined by (1.4) satisfies the identity
\[ \langle g, Tf \rangle = \langle Tg, f \rangle , \quad \forall g \in bL^1(E; m) , \]
(1.5)
where \( \langle g, f \rangle \) denotes the integral \( \int_E gf \mathrm{d}m \) for \( g \in L^1(E; m) \), \( f \in L^\infty(E; m) \). Consequently \( Tf \) is uniquely determined up to the \( m \)-equivalence for \( f \in L^\infty(E; m) \). \( T \) becomes a Markovian linear operator on \( L^\infty(E; m) \) and satisfies
\[ f_n, \ f \in L^\infty(E; m), \quad f_n \uparrow f \ [m], \quad n \to \infty \implies \lim_{n \to \infty} Tf_n = Tf \ [m] . \]
(1.6)

Further, if a sequence \( \{f_n\} \subset L^\infty(E; m) \) is uniformly bounded and converges to \( f \) \( m \)-a.e. as \( n \to \infty \), then
\[ \lim_{n \to \infty} \langle g, Tf_n \rangle = \langle g, Tf \rangle , \quad \forall g \in bL^1(E; m) . \]
(1.7)

**Lemma 1.6** (i) For any \( g \in L^\infty(E; m) \),
\[ T(g^2) - 2gTg + g^2T1 \geq 0 \quad [m] . \]
(ii) For any \( g \in L^\infty(E; m) \), define
\[ A_T(g) = \frac{1}{2} \int_E [T(g^2) - 2gTg + g^2T1] \mathrm{d}m + \int_E g^2(1 - T1) \mathrm{d}m . \]
(1.8)

It holds for \( g \in L^2(E; m) \cap L^\infty(E; m) \) that
\[ A_T(g) = (g - Tg, g) . \]
(1.9)

(iii) For any \( g \in L^\infty(E; m) \) and for any normal contraction \( \varphi \),
\[ A_T(\varphi \circ g) \leq A_T(g) . \]
(1.10)
Proof. Since $T(g^2) - 2sTg + s^2T^2 \geq 0$ for $g \in L^\infty$ and a simple function $s$, we get (i) by letting $s \to g$. (ii) can be shown first for $A_T^\perp(g) = (T(g^2) - 2sTg + g^2T^2, \eta_k) + (g^2(1 - T), \eta_k)$ by approximating $g$ with simple functions and using (1.7). We then let $k \to \infty$ to obtain (ii).

Let $\varphi^\ell$ be a specific sequence of normal contractions defined by

$$\varphi^\ell(t) = [(-\ell) \vee t] \land \ell, \quad t \in \mathbb{R}. \quad (1.11)$$

For any $m$-measurable function $g$ on $E$ with $|g| < \infty [m]$, $A_T(\varphi^\ell \circ g)$ is increasing as $\ell$ increases, as is clear from $\varphi^{\ell+1} \circ g = \varphi^\ell \circ g$ and Lemma 1.6 (iii). We can then extend the definition of $A_T(g)$ to $g$ by letting

$$A_T(g) = \lim_{\ell \to \infty} A_T(\varphi^\ell \circ g) \leq \infty. \quad (1.12)$$

Lemma 1.7 (i) For $g \in L^2(E;m)$, $A_T(g) = (g - Tg, g)$.

(ii) (Fatou’s property) For any $m$-measurable functions $g_n$, $g$ on $E$ with $|g_n| < \infty$, $|g| < \infty [m]$, $\lim_{n \to \infty} g_n = g [m]$, $A_T(g) \leq \liminf_{n \to \infty} A_T(g_n). \quad (1.13)$

(iii) For any $m$-measurable function $g$ on $E$ with $|g| < \infty [m]$ and for any normal contraction $\varphi$, $A_T(\varphi \circ g) \leq A_T(g)$.

Proof. (i) follows from Lemma 1.6 (ii) and the contraction property of $T$ on $L^2(E;m)$. Assertion (ii) for uniformly bounded $\{g_n\}$ can be shown in the same manner as the proof of [13, Prop.1] with a help of property (1.6). It then suffices to use the contraction $\varphi^\ell$. For the proof of (iii), we put $f = \varphi \circ g$, $f_\ell = \varphi \circ \varphi_\ell \circ g$. Then $f_\ell \to f$, $\ell \to \infty$, and it suffices to combine (ii) with (1.10).

More details of the proof of Lemma 1.6 and Lemma 1.7 are being given in [10] and [6].

Proof of Theorem 1.5 (i) For any $f \in \mathcal{F}_c$, take its approximating sequence $\{f_n\} \subset \mathcal{F}$. $f_n$ being $\mathcal{E}$-Cauchy, the triangular inequality guarantees the existence of the limit $\mathcal{E}(f, f) = \lim_{n \to \infty} \mathcal{E}(f_n, f_n)$. Let us prove that

$$1 \ell A_T(f) \uparrow \mathcal{E}(f, f) \quad t \downarrow 0, \quad (1.14)$$

which in particular implies that $\mathcal{E}(f, f)$ does not depend the choice of the approximating sequence.

Since $f - f_\ell \in \mathcal{F}_c$ for each $\ell$ and $\{f_n - f_\ell\} \subset \mathcal{F}$ is its approximating sequence, we have from Lemma 1.7

$$1 T A_T(f - f_\ell) \leq \liminf_{n \to \infty} 1 \ell A_T(f_n - f_\ell) \leq \lim_{n \to \infty} \|f_n - f_\ell\|_2^2.$$

Therefore $\lim_{\ell \to \infty} A_T(f - f_\ell) = 0$, and by the triangular inequality

$A_T(f) = \lim_{\ell \to \infty} A_T(f_\ell)$, which particularly implies the monotonicity of the left
hand side of (1.14) in \( t \). Since \( \lim_{t \to 0} \frac{1}{t} \mathcal{A}_R(f) = \| f \|_E^2 \), we can get from the triangular inequality and the inequality obtained above that
\[
\lim_{t \to 0} \sqrt{\frac{1}{t} \mathcal{A}_R(f) - \| f \|_E} \leq \lim_{t \to 0} \sqrt{\frac{1}{t} \mathcal{A}_R(f - f_t)} \leq \lim_{n \to \infty} \| f_n - f_t \|_E.
\]
The last term tends to 0 as \( \ell \to \infty \), yielding (1.14).
(ii) By Lemma 1.7 and (1.14), we have
\[
\frac{1}{t} \mathcal{A}_R(\varphi \circ f) \leq \frac{1}{t} \mathcal{A}_R(f) \leq \mathcal{E}(f, f), \quad \forall t > 0,
\]
and consequently, it is enough to prove that \( \varphi \circ f \in \mathcal{F}_E \). But this is an easy consequence of a Babach-Saks type theorem.

**Remark 1.8** Theorem 1.3 has been formulated in Bouleau-Hirsch [2] and in Ma-Röckner [12] without any topology on \( E \), while Theorem 1.5 was shown in Silverstein [15] and Fukushima-Oshima-Takeda [9] under a certain topological assumption on \( E \).

Let \( (\mathcal{E}, \mathcal{F}) \) be a Dirichlet form on \( L^2(E; m) \), \( (\mathcal{F}_E, \mathcal{E}) \) be its extended Dirichlet space and \( \{ T_t; t > 0 \} \) be the associated strongly continuous contraction semigroup of Markovian symmetric operators on \( L^2(E; m) \). We put
\[
S_t f = \int_0^t T_s f ds, \quad t > 0, \quad f \in L^2(E; m), \quad (1.15)
\]
the integral being taken in Bochner’s sense. \( S_t \) is a linear operator on \( L^2(E; m) \) and satisfies the boundedness \( ||S_t f||_2 \leq t ||f||_2, \quad f \in L^2(E; m) \).

Take \( f \in L^2(E; m) \cap L^1(E; m) \). Choose \( B_n \in (E) \) with \( m(B_n) < \infty, B_n \uparrow E \).
By the symmetry and the Markov property of \( T_t \),
\[
\int_{B_n} |T_t f(x)|m(dx) \leq (T_t||f||, 1_{B_n}) = (||f||, T_{t}1_{B_n}) \leq \int_E |f(x)| m(dx).
\]
Letting \( n \to \infty \), we get \( ||T_t f||_1 \leq ||f||_1 \). Similarly, we get \( ||S_t f||_1 \leq t ||f||_1 \) and hence both \( \{ T_t \} \), \( \{ S_t \} \) can be extended to linear operators on \( L^1(E; m) \) satisfying
\[
T_s T_t f = T_{s+t} f, \quad ||T_t f||_1 \leq ||f||_1, \quad ||S_t f||_1 \leq t ||f||_1, \quad f \in L^1(E; m).
\]
Further \( T_t \) and \( \frac{1}{t} S_t \) are Markovian.

Since \( S_t \) so extended satisfies for \( f \in L^1_+(E; m) \) the positivity and the monotonicity \( 0 \leq S_s f \leq S_t f, \quad [m], \quad 0 < s < t \), we can define a function \( Gf(x)(\leq \infty) \) by
\[
Gf(x) = \lim_{N \to \infty} S_N f(x), \quad f \in L^1_+(E; m), \quad (1.16)
\]
uniquely up to the \( m \)-equivalence.

**Definition 1.9** (i) \( \{ T_t; t > 0 \} \) is called **transient** if
\( Gg(x) < \infty \) \( [m] \), for some \( g \in L^1_+(E; m) \) with \( g > 0 \) \( [m] \).
(ii) \( \{ T_t; t > 0 \} \) is called **recurrent** if, for any \( f \in L^1_+(E; m) \), \( Gf(x) \) is either \( \infty \) or 0 \( [m] \), namely, \( m \{ x \in E : 0 < Gf(x) < \infty \} = 0 \).
It is known that the transience is equivalent to the condition that $G_f(x) < \infty \text{ [m]}$ for all $f \in L^1_+(E;m)$, while the recurrence is equivalent to $G_f(x) = \infty \text{ [m]}$ for all $f \in L^1(E;m)$ with $f > 0 \text{ [m]}$. We take the following theorem from [9] (cf. [15]).

**Theorem 1.10**  
(i) The transience of $\{T_t; t > 0\}$ is equivalent to one of the following conditions:

\[ u \in \mathcal{F}_e, \quad \mathcal{E}(u,u) = 0 \implies u = 0. \]  
\[ (\mathcal{F}_e, \mathcal{E}) \text{ is a real Hilbert space.} \]  
(ii) $\{T_t; t > 0\}$ is recurrent if and only if

\[ 1 \in \mathcal{F}_e, \quad \mathcal{E}(1,1) = 0. \]

2 The space of BL functions and Brownian motion

For a non-empty domain $D$ of the Euclidean $n$-space $\mathbb{R}^n$, we let

\[ D(u,v) = \sum_{i=1}^{n} \int_D \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_i} dx, \]  
\[ H^1(D) = \{ u \in L^2(D) : \frac{\partial u}{\partial x_i} \in L^2(D), \ 1 \leq i \leq n. \} \]  

Here the derivatives $\frac{\partial u}{\partial x_i}$, $1 \leq i \leq n$, are taken in Schwartz distribution sense and $L^2(D)$ denotes the $L^2$-space on $D$ based on the Lebesgue measure $dx$.

We focus our attention on a related space

\[ \text{BL}(D) = \left\{ T : \frac{\partial T}{\partial x_i} \in L^2(D), \ 1 \leq i \leq n \right\} \]  

of Schwartz distributions $T$. It is known that any distribution $T \in \text{BL}(D)$ can be identified with a function in $L^2_{\text{loc}}(D)$ (cf. L. Schwartz [14], J. Deny and J.L. Lions [8]) so that

\[ \text{BL}(D) = \{ u \in L^2_{\text{loc}}(D) : \frac{\partial u}{\partial x_i} \in L^2(D), \ 1 \leq i \leq n, \} \]  

where again the derivatives are taken in Schwartz distribution sense. Members in $\text{BL}(D)$ are called BL (Beppo-Levi) functions on $D$. The space $\text{BL}(D)$ is known to enjoy the following properties (cf. [8]):

(BL.1) The quotient space $\hat{\text{BL}}(D)$ of $\text{BL}(D)$ by the subspace of constant functions is a Hilbert space with inner product $D$. Any $D$-Cauchy sequence $u_n \in \text{BL}(D)$ admits $u \in \text{BL}(D)$ and constants $c_n$ such that $u_n$ is $D$-convergent to $u$ and $u_n + c_n$ is $L^2_{\text{loc}}$-convergent to $u$.

(BL.2) A function $u$ on $D$ is in $\text{BL}(D)$ if and only if, for each $i$ ($1 \leq i \leq n$), there is a version $u^{(i)}$ of $u$ such that it is absolutely continuous on almost all straight lines parallel to $x_i$-axis and the derivative $\frac{\partial u^{(i)}}{\partial x_i}$ in the ordinary sense (which exists a.e. on $D$) is in $L^2(D)$. In this case, the ordinary derivatives coincide with the distribution derivatives of $u$. 

6
Notice that the version \( u^{(i)} \) in the above for \( u \in \text{BL}(D) \) depends on the choice of the coordinate \( x_i \). However each \( u \in \text{BL}(D) \) admits a quasi continuous version \( \tilde{u} \) called a BLD (Beppo Levi-Deny) function, which enjoys the absolute continuity property (BL.2) no matter how the coordinates are chosen (cf. [8]).

The space \( H^1(D) = \text{BL}(D) \cap L^2(D) \) is called the Sobolev space of order 1 on \( D \).

\[
(\mathcal{E}, \mathcal{F}) = \left( \frac{1}{2} \mathcal{D}, H^1(D) \right)
\]

is a closed symmetric form on \( L^2(D) \). To see this, suppose \( \{u_n\} \subset \mathcal{F} \) is \( \mathcal{E}_1 \)-Cauchy. Then \( \frac{\partial u_n}{\partial x_i} \) is \( L^2(D) \)-convergent to some \( v_i \in L^2(D) \) for each \( 1 \leq i \leq n \) and \( u_n \) is \( L^2(D) \)-convergent to some \( u \in L^2(D) \). Then, for any \( f \in C_0^\infty \),

\[
(v_i, f) = \lim_{n \to \infty} \left( \frac{\partial u_n}{\partial x_i}, f \right) = -\lim_{n \to \infty} \left( u_n, \frac{\partial f}{\partial x_i} \right) = -(u, \frac{\partial f}{\partial x_i})
\]

and hence \( v_i = \frac{\partial u}{\partial x_i}, \ 1 \leq i \leq n \). It is a Dirichlet form on \( L^2(D) \) because its Markov property (1.2) can be verified by a direct use of the property (BL.2).

Let us denote by \( H^1_\mathcal{E}(D) \) the extended Dirichlet space of the Dirichlet form (2.5). When \( D = \mathbb{R}^n \), the Dirichlet form (2.5) on \( L^2(\mathbb{R}^n) \) is associated with the transition density \( g_t(x) = (2\pi t)^{-n/2} \exp(-|x|^2/(2t)) \) of the \( n \)-dimensional standard Brownian motion. Since \( \int_0^\infty g_t(x) dt, x \neq 0 \), is divergent when \( n = 1, 2 \), but convergent and equal to the Newtonian kernel \( N(x) \) when \( n \geq 3 \), the corresponding \( L^2 \)-semigroup is recurrent in the former case and transient in the latter case.

When \( n \geq 3 \), the extended Dirichlet space \( (H^1_\mathcal{E}(\mathbb{R}^n), \mathcal{E}) \) of (2.5) for \( D = \mathbb{R}^n \) is a real Hilbert space and

\[
u \in H^1_\mathcal{E}(\mathbb{R}^n), \ \mathcal{E}(u, u) = 0 \implies u = 0,
\]

in view of Theorem 1.10.

**Theorem 2.1** Assume that \( n \geq 3 \), \( \text{BL}(\mathbb{R}^n) \) is the linear space spanned by \( H^1(\mathbb{R}^n) \) and constant functions. The space \( (H^1_\mathcal{E}(\mathbb{R}^n), \mathcal{E}) \) is isometric with the space \( (\text{BL}(\mathbb{R}^n), \frac{1}{2} \mathcal{D}) \) by the canonical map \( \text{BL}(\mathbb{R}^n) \mapsto \text{BL}(\mathbb{R}^n) \).

**Proof.** For \( u \in H^1_\mathcal{E}(\mathbb{R}^n) \), there is a sequence \( \{u_n\} \subset H^1(\mathbb{R}^n) \) which is \( \mathcal{D} \)-Cauchy and convergent to \( u \) a.e. \( \mathcal{D}(u_n, u_n) \) then converges to \( \mathcal{E}(u, u) \). By (BL.1), there exist \( v \in \text{BL}(\mathbb{R}^n) \) and constants \( c_n \) such that \( \{u_n\} \) is \( \mathcal{D} \)-convergent to \( v \) and the sequence \( \{u_n + c_n\} \) is convergent to \( v \) in \( L^2_{\text{loc}}(\mathbb{R}^n) \). By choosing a subsequence if necessary, we may assume that the latter sequence converges to \( v \) a.e. Then \( \lim_{n \to \infty} c_n = c \) exists, \( u = v - c \) and consequently, \( u \in \text{BL}(\mathbb{R}^n) \) and \( \mathcal{E}(u, u) = \mathcal{D}(u, u) \). Further we see from (2.6) that the Hilbert space \( (H^1_\mathcal{E}(\mathbb{R}^n), \mathcal{E}) \) is isometrically imbedded into a closed subspace of \( (\text{BL}(\mathbb{R}^n), \frac{1}{2} \mathcal{D}) \) by the canonical map \( \text{BL}(\mathbb{R}^n) \mapsto \text{BL}(\mathbb{R}^n) \). We denote by \( \hat{u} \) the equivalence class represented by \( u \in \text{BL}(\mathbb{R}^n) \).

If \( \hat{u} \in \text{BL}(\mathbb{R}^n) \) is \( \mathcal{D} \)-orthogonal to this closed subspace, then, since \( C_0^\infty(\mathbb{R}^n) \subset H^1(\mathbb{R}^n) \), we have

\[
(\Delta u, f) = -\mathcal{D}(u, f) = 0, \ \forall f \in C_0^\infty(\mathbb{R}^n),
\]
which implies that $\Delta u = 0$, namely, (a version of) $u$ is harmonic on $\mathbb{R}^n$. Since the ordinary derivatives $\frac{\partial u}{\partial x_i}$, $1 \leq i \leq n$, are also harmonic on $\mathbb{R}^n$, we get from the mean-value theorem the estimate

$$\left| \frac{\partial u}{\partial x_i} (x) \right| \leq \frac{1}{|B_r(x)|} \int_{B_r(x)} \left| \frac{\partial u}{\partial x_i} \right| \, dx \leq \left( \frac{1}{|B_r(x)|} \mathbf{D}(u, u) \right)^{1/2}, \quad x \in \mathbb{R}^n,$$

where $B_r(x)$ is the ball of radius $r$ centered at $x$ and $|B_r(x)|$ denotes its volume. By letting $r \to \infty$, we see that all derivatives of $u$ vanish and hence $u$ is constant, and consequently $\dot{u}$ is the 0 element of $\text{BL}(\mathbb{R}^n)$. \hfill $\square$

**Remark 2.2** Example 1.5.3 and Example 6.2.1 of Fukushima-Oshima-Takeda [9] contained incorrect statements that, when $n \geq 3$, the space $H^1_0(\mathbb{R}^n)$ is obtained from $\text{BL}(\mathbb{R}^n)$ by removing non-zero constant functions. Taking this opportunity, we would like mention that they should be corrected as the statement of Theorem 2.1 of the present paper.

We next consider, on a general domain $D \subset \mathbb{R}^n$, a measure $m(dx) = m(x)dx$ with a density function $m(x)$ satisfying

$$m(x) > 0 \quad \forall x \in D, \quad m \in bC(D) \cap L^1(D) \quad (2.7)$$

and an associated form

$$(\mathcal{E}, \mathcal{F}) = \left( \frac{1}{2} \mathbf{D}, \text{BL}(D) \cap L^2(D; m) \right), \quad (2.8)$$

which is obtained just by replacing $L^2(D)$ with $L^1(D; m)$ in (2.5). Since the convergence in $L^2(D; m)$ implies the convergence in $L^2_{\text{loc}}(D)$, (2.8) can be readily seen to be a Dirichlet form on $L^2(D; m)$.

**Theorem 2.3** The Dirichlet form (2.8) on $L^2(D; m)$ is recurrent. Its extended Dirichlet space $(\mathcal{F}_e, \mathcal{E})$ coincides with the space $(\text{BL}(D), \frac{1}{2} \mathbf{D})$.

**Proof.** Since $m$ is assumed to be a finite measure on $D$, the present Dirichlet form enjoys the recurrence condition (1.19). We further have

$$u \in \mathcal{F}_e, \quad \mathcal{E}(u, u) = 0 \implies u \text{ is constant a.e.} \quad (2.9)$$

To see this, suppose $u \in \mathcal{F}_e$, $\mathcal{E}(u, u) = 0$ and put $u_\ell = \varphi^\ell \circ u$ by the contraction $\varphi^\ell$ of (1.11). Then $u_\ell \in L^2(E; m) \cap \mathcal{F}_\ell = \mathcal{F}$ and hence $\frac{1}{2} \mathbf{D}(u_\ell, u_\ell) = \mathcal{E}(u_\ell, u_\ell) = 0$. Therefore $u_\ell$ is a constant and we get (2.9) by letting $\ell \to \infty$.

Denote by $\overline{\mathcal{F}}_e$ the quotient space of $\mathcal{F}_e$ by the subspace of constant functions. Just as in the proof of the preceding theorem but using (2.9) in place of (2.6), we conclude that the space $(\overline{\mathcal{F}}_e, \mathcal{E})$ is isometrically embedded into the space $(\text{BL}(D), \frac{1}{2} \mathbf{D})$.

Take any $u \in \text{BL}(D)$ and put $u_\ell = \varphi^\ell \circ u$ as above. By (BL.2), $u_\ell \in \text{BL}(D)$ and

$$\mathbf{D}(u - u_\ell, u - u_\ell) = \int_{\{x : |u(x)| > \ell\}} |\nabla u|^2 \, dx \to 0, \quad \ell \to \infty.$$
Since \( u_t \in \mathcal{F} \) and \( u_t \) converges to \( u \) pointwise, \( u \) must be an element of \( \mathcal{F}_c \). Hence the above isometric embedding is an onto map and \( \mathcal{F}_c = \text{BL}(D) \).  

When the Lebesgue measure of the domain \( D \) is finite, then we can take \( m(dx) \) to be the Lebesgue measure in (2.8) in reducing \( \mathcal{F} \) to \( H^1(D) \). Hence

**Corollary 2.4** If the domain \( D \) is of finite Lebesgue measure, then

\[
H^1(D) = \text{BL}(D). \tag{2.10}
\]

Finally, when \( D = \mathbb{R}^n \) and \( m \) is a finite measure on \( \mathbb{R}^n \) with density satisfying (2.7) on \( \mathbb{R}^n \), we designate the Dirichlet form (2.8) on \( L^2(\mathbb{R}^n; m) \) as

\[
(\mathcal{E}^*, \mathcal{F}^*) = \left( \frac{1}{2} \mathbf{D}, \text{BL}(\mathbb{R}^n) \cap L^2(\mathbb{R}^n; m) \right). \tag{2.11}
\]

In parallel to this, let us consider the symmetric form on \( L^2(\mathbb{R}^n, m) \) defined by

\[
(\mathcal{E}^{(0)}, \mathcal{F}^{(0)}) = \left( \frac{1}{2} \mathbf{D}, H^1(\mathbb{R}^n) \cap L^2(\mathbb{R}^n; m) \right), \tag{2.12}
\]

which is known to be the Dirichlet form associated with the \( n \)-dimensional Brownian motion being time changed by its additive functional \( A_t = \int_0^t m(X_s)ds \) (cf. [9, Example 6.2.1]).

Assume that \( n \geq 3 \). Then they are different; (2.11) is recurrent while (2.12) is transient. Further we see from Theorem 2.1 that

\[
\mathcal{F}^* = \{ u = u_0 + c : u_0 \in \mathcal{F}^{(0)}, \ c \text{ is constant} \}, \quad \mathcal{E}^*(u, u) = \mathcal{E}^{(0)}(u_0, u_0). \tag{2.13}
\]

Let \( \mathbb{R}^n_+ = \mathbb{R}^n \cup \{ \infty \} \) be the one-point compactification of \( \mathbb{R}^n \) and \( m^* \) be the extension of \( m \) from \( \mathbb{R}^n \) to \( \mathbb{R}^n_+ \) with \( m^*(\{ \infty \}) = 0 \). By identifying \( L^2(\mathbb{R}^n; m) \) with \( L^2(\mathbb{R}^n_+; m^*) \), we can regard \( (\mathcal{E}^*, \mathcal{F}^*) \) as a Dirichlet form on \( L^2(\mathbb{R}^n_+; m^*) \).

**Theorem 2.5** When \( n \geq 3 \), \( (\mathcal{E}^*, \mathcal{F}^*) \) is a strongly local regular Dirichlet form on \( L^2(\mathbb{R}^n_+, m^*) \).

Indeed, if we let \( \mathcal{C} = \{ u + c : u \in C_0(\mathbb{R}^n), \ c \text{ is constant} \} \), then \( \mathcal{C} \subset C(\mathbb{R}^n_+) \) and \( \mathcal{C} \) is readily seen to be a core of the Dirichlet form \( (\mathcal{E}^*, \mathcal{F}^*) \). The strong locality of \( (\mathcal{E}^*, \mathcal{F}^*) \) can be proved in the same way as in the proof of Theorem 3.2 of [11], where a Dirichlet form quite similar to (2.13) was studied in a rather general context.

The \( m^* \)-symmetric diffusion process \( X^* \) on \( \mathbb{R}^n_+ \) associated with the Dirichlet form of Theorem 2.5 is an extension of the time changed Brownian motion \( X^0 \) on \( \mathbb{R}^n \) associated with \( (\mathcal{E}^{(0)}, \mathcal{F}^{(0)}) \). \( X^0 \) approaches to \( \infty \) at a finite life time \( \zeta^0 \) with mean \( \mathbb{E}_x[\zeta^0] \) being equal to the Newtonian potential \( N \ast m(x) \) of the function \( m \). \( X \) is obtained by prolonging the path of \( X^0 \) after \( \zeta^0 \) with a specific reflection at \( \infty \) by piecing together the excursions of \( X^0 \) around \( \infty \). Such a probabilistic construction has been studied in [11] and [4]. The relationship between \( (\mathcal{E}^*, \mathcal{F}^*) \) and \( (\mathcal{E}^{(0)}, \mathcal{F}^{(0)}) \) will be studied in terms of the reflected Dirichlet space in [5].

**Acknowledgement** The author would like to express his hearty thanks to Professors Lucian Beznea, Nicu Boboc and Gheorghe Bucur for kindly inviting him to the International Conference on Potential Theory and Stochastics dedicated to the memory of Aurel Cornea, held at Albac, Romania in September, 2007.
